Medical Summary [redacted] File No.: B#25 - 1, 2, 3, 4

The drug used in this case was Sodium Amytal and was given intravenously. No stimulant was administered.

One unusual feature in this case was that the Subject, during the third Polygraph run, refused to answer questions or to speak. He was then informed that a sedative would be necessary in order to again test him with the machine.

Under the influence of Sodium Amytal, he gave a wealth of information which he had carefully concealed when interrogated either with or without the D. D. machine. The Subject slept overnight instead of being given a stimulant. He was examined the following morning without the use of medication. He apparently had complete amnesia for the utilization of the drug and for any information given while under the effect of the medication.
