DESOXYN

Desoxyn - A proprietary brand of d-desoxyephedrine hydrochloride.

Desoxyephedrine - This drug is employed in the form of d-desoxyephedrine hydrochloride to decrease the sense of fatigue, counteract sleepiness, and produce elevation of mood.

This drug was employed in the second test on the second case in the Artichoke operation in [redacted] in June 1952. The drug was administered by [redacted], working with [redacted], and was injected into the Gilson apparatus by inserting a needle into the rubber tube top which was in turn inserted by a needle into a vein in the arm of the subject. The drug was used after heavy dosages of sodium pentothal had placed the subject in a drowsy, "twilight condition" and after a number of minutes of interrogation under this condition had been carried out. [redacted] suggested the use of the drug at this time to produce a more uninhibited state and to make the subject more talkative and more relaxed. The drug (in combination with sodium pentothal) as noted above had a dramatic effect in that it made the subject very talkative, expansive, and produced a very remarkable regression which carried the subject back over a period of 15 years and made the subject believe that the interpretor [redacted] was an old and trusted associate.

The sodium pentothal coupled with the Desoxyn worked for a period of two hours with excellent results and although heavy dosages of sodium pentothal were used initially, very small amounts only of the Desoxyn were used.

In connection with the above, exact amounts of pentothal, Desoxyn, etc. are to be found in the medical reports to be submitted by [redacted] and [redacted].

On the basis of the results in this case, it is felt that Desoxyn and other drugs which are closely related to this compound should be considered for future exploration both in research and actual case work in the future.
